[Coupling metrics to diagnose land-atmosphere interactions]

Granger Causality

- Principle:
  - This is a general statistical principal not specific to land-atmosphere coupling. It comes from the field of econometrics –models are formed with and without an input S (e.g., soil moisture) and a significant difference in response indicates the causality of S.
  - For the potential dependence of precipitation P on soil moisture S, the conditional distributions tested are:

$$F(P_t \mid W_{t-\Delta t}) \neq F(P_t \mid W_{t-\Delta t} - S_{t-\Delta t})$$

    within some range of confidence, where $W_{t-\Delta t}$ is all knowledge available up to time $t - \Delta t$ (which includes previous precipitation, soil moisture and potentially other variables as well) and $W_{t-\Delta t} - S_{t-\Delta t}$ means all knowledge except that of soil moisture.
    - $W_{t-\Delta t}$ must not contain any future information from t or later,
    - $W_{t-\Delta t}$ must not contain redundant information (e.g., multiple functionally-related variables)

- Data needs:
  - Observational or model data can be used – multiple linear regression or other models are common. The method is non-restrictive, however, as long as two conditional distributions can be constructed and statistically tested.

- Observational data sources:
  - Observed soil moisture and precipitation (or any data pertinent to the causality test).

- Caveats:
  - Care must be taken to avoid detection of false causal relationships (e.g., effect-effect relationships or apparent causation due to persistence).
